

Elementary Statistics

Three approaches to looking up z -scores

1 Using Technology

1.1 TI-83 or TI-84 (plus)

First turn on your calculator and press 2nd then VARS. This takes you to the DISTR menu.

- To compute the area above/below/between given value(s) for the normal curve with mean μ and standard deviation σ , select the second option, **normalcdf** then enter the following parameters:
 - For the percentage between values a and b (with $a < b$), enter the parameters in this order: a, b, μ, σ . (Note: Your calculator may give these parameters names: lower, upper, μ, σ .)
 - For the percentage above (to the right of) a value a , enter the parameters in this order: $a, 10 \wedge 99, \mu, \sigma$.
 - For the percentage below (to the left of) a value b , enter the parameters in this order: $-10 \wedge 99, b, \mu, \sigma$. (Note: The - sign you need to enter for $-10 \wedge 99$ is the button next to the period on the bottom row of buttons, not the - sign you use for subtraction on the left side near the addition and multiplication buttons.)
 - **Important Note:** a and b need to be in terms of the data values, not z -scores. If you want to enter the z -scores, use $\mu = 0$ and $\sigma = 1$, not the average and standard deviation for your data.
- To find the z -score with the p th percentile, select the third option from the DISTR menu, **invNorm**, then enter the p value and leave the default values $\mu = 0$ and $\sigma = 1$.
- To find the data value (not the z -score but the actual value) with the p th percentile, select the third option from the DISTR menu, **invNorm**, then enter the p value, and change the default values to the μ and σ for the distribution you're using.

1.2 Microsoft Excel

- For the percentage below (to the left of) a value x with mean μ and standard deviation σ , use the following formula in Excel:
`=NORMDIST($x, \mu, \sigma, \text{TRUE}$)`
- To find the value associated with a given percentile p with mean μ and standard deviation σ , use the following formula in Excel:
`=NORMINV(p, μ, σ)`
 - **Important Note:** Enter your percentile p as a decimal, not as a percentage. For example, if you want to know for what value 45% of the data lies below it, enter `=NORMINV(0.45, μ,σ)`
- Note: The above formulas will work for the data values. If you wish to input z -scores instead, use $\mu = 0$ and $\sigma = 1$.

2 Using the z Table

The classical way to compute percentiles for z -scores and z -scores for percentiles is to look it up in a pre-calculated table. This table appears on the next two pages. The first table corresponds to negative z -scores; the second table corresponds to positive z -scores. For the negative z -score table, the z -scores appear down the right side of the table (with an additional digit of accuracy given across the top), and the percentage of the data that lies below that z -score is the value given in the middle of the table. The positive z -score table works in the same way, but with the z -scores down the left hand side of the table rather than the right hand side.

For example, a z -score of -1.63 lies above 5.16% of the data, and a z -score of 2.76 lies above 99.71% of the data. Look at the tables and be sure you understand how to read the table to get these values.

If you need to know what z -score corresponds to the 80th percentile of data, find the value closest to 80% (0.8000) in the middle of the tables, then read the z -score from the side and top. In this example, the values 0.7995 and 0.8023 appear in the table. Since 0.7995 is closer to 80% than 0.8023, we will use that z -score, which is 0.84. (0.7995 is in the 0.8 row and the 0.04 column)

Note: For z -scores less than -3.9, the percentile is estimated at 0.00% to two decimal places (but it is not exactly equal to 0%). For z -scores greater than 3.9, the percentile is estimated at 100.00% to two decimal places (but is not exactly equal to 100%).
